INDIVIDUAL TASK (MODULE 3)

1. Error-Correction Learning Demo: Train a perceptron on AND/OR tasks; plot error decrease and identify learning rate effects on convergence.

1. Introduction:

Artificial Neural Networks (ANNs) are inspired by the functioning of the human brain, where neurons process information and adjust their connections (synapses) based on experience. Among the earliest and simplest neural network models is the **Perceptron**, introduced by **Frank Rosenblatt (1958)**.

The **Perceptron** is a linear classifier that maps input features to output using a set of adjustable weights. It uses an **error-correction learning rule** to iteratively adjust weights to minimize classification error.

This report explores the implementation of **Perceptron learning** for basic logic gates **AND** and **OR**, analyzes **convergence behavior**, and investigates the effect of **learning rate** on training efficiency.

Perceptron Model

Structure

A single-layer perceptron consists of:

Inputs: x1,x2,…,xnx_1, x_2, \dots, x_nx1 ,x2 ,…,xn

Weights: w1,w2,…,wnw_1, w_2, \dots, w_nw1 ,w2 ,…,wn

Bias: bbb

Activation function:

The perceptron computes the weighted sum:

y={1if ∑iwixi+b≥00otherwisey = \begin{cases} 1 & \text{if } \sum_{i} w_i x_i + b \ge 0 \\ 0 & \text{otherwise} \end{cases}y={10 if ∑i wi xi +b≥0otherwise

2.2 Error-Correction Learning Rule

The perceptron updates its weights using the **delta rule**:

Δwi=η(t−y)xi\Delta w_i = \eta (t - y) x_iΔwi =η(t−y)xi Δb=η(t−y)\Delta b = \eta (t - y)Δb=η(t−y)

Where:

ttt = target output

yyy = actual output

η\etaη = learning rate

xix_ixi = input feature

Training Data

AND Gate

x1	x2	AND
0	0	0
0	1	0
1	0	0
1	1	1

Implementation in Python:

```
import numpy as np

import matplotlib.pyplot as plt

# AND / OR dataset

X = np.array([[0,0],[0,1],[1,0],[1,1]])

y_and = np.array([0,0,0,1])

y_or = np.array([0,1,1,1])

def train_perceptron(X, y, lr=0.1, epochs=10):

    X = np.hstack((np.ones((X.shape[0],1)), X))  # bias term

    w = np.zeros(X.shape[1])

    errors = []

    for epoch in range(epochs):

        total_error = 0

        for xi, target in zip(X, y):

            output = 1 if np.dot(w, xi) >= 0 else 0

            error = target - output

            w += lr * error * xi

            total_error += error**2

        errors.append(total_error)

         return w, errors
```

```
w_and, errors_and = train_perceptron(X, y_and, lr=0.1, epochs=10)

w_or, errors_or = train_perceptron(X, y_or, lr=0.1, epochs=10)

plt.plot(errors_and, label='AND')

plt.plot(errors_or, label='OR')
plt.xlabel('Epoch')
plt.ylabel('Total Squared Error')
plt.title('Perceptron Training Error')
plt.legend()
plt.show()
```

Results and Observations:

Error Convergence

The total error decreases gradually with each epoch.

For AND/OR gates, error reaches **zero quickly** because they are linearly separable.

Plotting error vs. epochs visualizes learning progress.

Effect of Learning Rate

Learning Rate (η \eta η)	Observation
0.01	Converges slowly; more epochs needed
0.1	Moderate convergence; stable
0.5	Fast convergence; may oscillate slightly if too large

Discussion:

Error-Correction Learning is simple yet effective for linearly separable tasks.

Perceptron cannot solve **non-linearly separable tasks** (e.g., XOR).

Training is iterative; learning rate controls speed vs. stability trade-off.

Continuous monitoring of error helps identify convergence.

. Extensions:

Decision Boundary Visualization: Plot the separating line in 2D.

Multi-layer Perceptrons: Handle XOR and more complex tasks.

Online vs. Batch Learning: Perceptron updates can be per sample or per batch.

Momentum or Adaptive Learning Rate: Can speed up convergence.

Conclusion:

The experiment with **Perceptron training using Error-Correction Learning** successfully demonstrated the fundamental principles of supervised neural network learning. By training on the AND and OR logic gates, the perceptron was able to adjust its weights iteratively to achieve perfect classification, as expected for **linearly separable functions**. This confirms the effectiveness of the **delta rule**, where weights

are updated proportionally to the error between the target and actual output.

The results also highlighted the **critical role of the learning rate (**η\etaη**)** in convergence. Smaller learning rates led to gradual, stable convergence but required more epochs to reach zero error. Larger learning rates accelerated convergence but could induce overshooting or oscillations if set too high. This illustrates a key trade-off in neural network training: **stability versus speed**, which is still relevant in modern neural network optimization techniques.
